The pneumatic tire includes a plurality of circumferential main grooves and extending in the tire circumferential direction, and a plurality of land portions partitioned by the circumferential main grooves. One row of the land portion includes a plurality of lug grooves that pass through the land portion in the tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and a plurality of blocks partitioned by the lug grooves. Also, the lug groove includes a first lug groove portion and at least one second lug groove portion opening into one of the circumferential main grooves. Also, the groove width b of the first lug groove portion and the groove width B of the second lug groove portion have the relationships of $2.0\text{ mm} \leq b \leq 5.0\text{ mm}$, $5.0\text{ mm} \leq B \leq 10.0\text{ mm}$, and $b < B$.

FIG. 10B

1

PNEUMATIC TIRE

TECHNICAL FIELD

The present technology relates to a pneumatic tire, and more particularly relates to a pneumatic tire that can improve the snow braking performance and rolling resistance performance.

BACKGROUND

In radial tires for heavy loads mounted on trucks and buses and the like, a block pattern is adopted in order to increase the braking performance (snow braking performance) on snow-covered road surfaces. On the other hand, in the case of radial tires for heavy loads, there is a demand to reduce the rolling resistance in order to improve the fuel economy. Generally, the snow braking performance is excellent in the case of tread patterns based on ribs, and the fuel economy is excellent in the case of tread patterns based on blocks. Therefore, the two have conflicting properties.

Note that as a conventional pneumatic tire having a block pattern, the technology described in International Patent Publication No. WO/2008/146851 is known.

SUMMARY

The present technology provides a pneumatic tire that is capable of improving the tire snow braking performance and the rolling resistance performance.

The pneumatic tire according to the present technology includes a plurality of circumferential main grooves extending in the tire circumferential direction; and a plurality of land portions partitioned by the circumferential main grooves, wherein the land portion in at least one row includes a plurality of lug grooves that pass through the land portion in the tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and a plurality of blocks partitioned by the plurality of lug grooves, the lug grooves include a first lug groove portion, and at least one second lug groove portion that opens to one of the circumferential main grooves, and, the groove width b of the first lug groove portion and the groove width B of the second lug groove portion have the relationships of $2.0\text{ mm} \leq b \leq 5.0\text{ mm}$ and $b < B$, and are within ranges such that during ground contact of the blocks, the first lug groove portions are closed and the second lug groove portions are not closed but remain open.

In the pneumatic tire according to the present technology, the first lug groove portion has the narrow groove width b , so when the blocks contact the ground, the first lug groove portion is closed and the blocks become connected in the tire circumferential direction. Accordingly, the stiffness in the tire circumferential direction of the center land portion increases, and the tire rolling resistance is reduced. On the other hand, the wide second lug groove portion is disposed at the edge of the center land portion, so the edge component of the center land portion is ensured, and the tire snow braking performance is ensured. Accordingly, there is the advantage that both the tire rolling resistance performance and the snow braking performance are achieved.

BRIEF DESCRIPTION OF THE DRAWING(S)

FIG. 1 is a cross-sectional view in a tire meridian direction illustrating a pneumatic tire according to an embodiment of the present technology.

2

FIG. 2 is a plan view illustrating a tread surface of the pneumatic tire depicted in FIG. 1.

FIG. 3 is an explanatory view illustrating the main parts of the pneumatic tire depicted in FIG. 2.

FIG. 4 is an explanatory view illustrating the effect of the pneumatic tire depicted in FIG. 1.

FIG. 5 is an explanatory view illustrating a modified example of the pneumatic tire depicted in FIG. 1.

FIG. 6 is an explanatory view illustrating a modified example of the pneumatic tire depicted in FIG. 1.

FIG. 7 is an explanatory view illustrating a modified example of the pneumatic tire depicted in FIG. 1.

FIG. 8 is an explanatory view illustrating a modified example of the pneumatic tire depicted in FIG. 1.

FIGS. 9A-9B include a table showing results of performance testing of pneumatic tires according to embodiments of the present technology.

FIGS. 10A-10B include a table showing results of performance testing of pneumatic tires according to embodiments of the present technology.

DETAILED DESCRIPTION

The present technology is described below in detail with reference to the accompanying drawings. However, the present technology is not limited to these embodiments. Moreover, constituents which can possibly or obviously be substituted while maintaining consistency with the present technology are included in constitutions of the embodiments. Furthermore, a plurality of modified examples that are described in the embodiment can be freely combined within a scope of obviousness for a person skilled in the art.

Pneumatic Tire

FIG. 1 is a cross-sectional view in a tire meridian direction illustrating a pneumatic tire according to an embodiment of the present technology. FIG. 1 illustrates a region on one side of a cross-section in the tire radial direction. As an example of a pneumatic tire, FIG. 1 illustrates a radial tire for heavy loads mounted on a steering axle of a truck, bus, and the like for long-distance transport. Note that the symbol CL refers to a tire equator plane. A tire width direction refers to a direction parallel to a tire rotational axis (not illustrated), and the tire radial direction refers to the direction perpendicular to the tire rotational axis.

The pneumatic tire 1 has an annular structure centered around the tire rotational axis, and includes a pair of bead cores 11, 11, a pair of bead fillers 12, 12, a carcass layer 13, a belt layer 14, a tread rubber 15, a pair of side wall rubbers 16, 16, and a pair of rim cushion rubbers 17, 17 (see FIG. 1).

The pair of bead cores 11, 11 have annular structures and constitute cores of left and right bead portions. The pair of bead fillers 12, 12 are formed from a lower filler 121 and an upper filler 122, and are disposed on a periphery of each of the pair of bead cores 11, 11 in the tire radial direction so as to reinforce the bead portions.

The carcass layer 13 stretches between the left and right side bead cores 11 and 11 in toroidal form, forming a framework for the tire. Additionally, both ends of the carcass layer 13 are folded from an inner side in a tire width direction toward an outer side in the tire width direction and fixed so as to wrap around the bead cores 11 and the bead fillers 12. Also, the carcass layer 13 is constituted by a plurality of carcass cords formed from steel or organic fibers (e.g., nylon, polyester, rayon, or the like) covered by a coating rubber and subjected to a rolling process, and has a carcass angle (inclination angle of the carcass cord in a fiber direction with respect to the

tire circumferential direction), as an absolute value, of not less than 85° and not more than 95°.

The belt layer **14** is formed by laminating a plurality of belt plies **141** to **144**, and is disposed to extend over a periphery of the carcass layer **13**. The belt plies **141** to **144** are configured from, for example, a large angle belt **141**, a pair of cross belts **142**, **143**, and a belt cover **144**. Also, each of the belt plies **141** to **144** is configured by a plurality of belt cords formed from steel or organic fibers, covered by coating rubber, and subjected to a rolling process, having a predetermined belt angle (angle of inclination of belt cord fiber direction with respect to the tire circumferential direction).

The tread rubber **15** is disposed on an outer circumference in the tire radial direction of the carcass layer **13** and the belt layer **14**, and forms a tread portion of the tire. The pair of side wall rubbers **16**, **16** is disposed on each outer side of the carcass layer **13** in the tire width direction, so as to form left and right sidewall portions of the tire. The pair of rim cushion rubbers **17** and **17** is disposed on each outer side of the left and right bead cores **11** and **11** and the bead fillers **12** and **12** in the tire width direction so as to form left and right bead portions of the tire.

FIG. 2 is a plan view illustrating a tread surface of the pneumatic tire depicted in FIG. 1. FIG. 2 illustrates a tread pattern for an all weather tire. The tire circumferential direction is the direction around the tire rotational axis.

The pneumatic tire **1** includes a plurality of circumferential main grooves **21**, **22** extending in the tire circumferential direction, a plurality of land portions **31** to **33** partitioned by the circumferential main grooves **21**, **22**, and a plurality of lug grooves **41** to **43** disposed in the land portions **31** to **33** (see FIG. 2).

Circumferential main groove refers to a circumferential groove having a groove width of not less than 5.0 mm. Moreover, “lug grooves” refers to lateral grooves having a groove width of 2.0 mm or greater. When measuring these groove widths, the notch and the chamfered portion formed in the groove opening portion are omitted. Lateral grooves or slits having a groove width of less than 2.0 mm are classified as sipes.

For example, the pneumatic tire **1** is provided with four circumferential main grooves **21**, **22** having a zigzag shape in the configuration in FIG. 2, disposed so as to have left-right symmetry with respect to the tire equatorial plane CL. Additionally, one center land portion **31**, a pair of left and right second land portions **32**, **32**, and a pair of left and right shoulder land portions **33**, **33** are partitioned by these circumferential main grooves **21**, **22**. Also, all the land portions **31** to **33** have a plurality of lug grooves **41** to **43** respectively that extend in the tire width direction. Also, the lug grooves **41** to **43** have an open structure that passes through the land portions **31** to **33** in the tire width direction, and are arranged with a predetermined interval in the tire circumferential direction. Accordingly, all the land portions **31** to **33** are rows of blocks divided into a plurality of blocks **51** to **53**.

[First Lug Groove Portion and Second Lug Groove Portion of the Lug Grooves]

In radial tires for heavy loads mounted on trucks and buses and the like, a block pattern is adopted in order to increase the braking performance (snow braking performance) on snow-covered road surfaces. On the other hand, in the case of radial tires for heavy loads, there is a demand to reduce the rolling resistance in order to improve the fuel economy. Generally, the snow braking performance is excellent in the case of tread patterns based on ribs, and the fuel economy is excellent in the case of tread patterns based on blocks. Therefore, the two have conflicting properties.

Therefore, the following configuration has been adopted on this pneumatic tire **1** in order to achieve both snow braking performance and fuel economy.

FIG. 3 is an explanatory view illustrating the main parts of the pneumatic tire depicted in FIG. 2. In FIG. 3, a pair of blocks **51**, **51** that are adjacent in the center land portion **31** and a single lug groove **41** that is interposed between these blocks **51**, **51** have been extracted.

In the pneumatic tire **1**, as illustrated in FIG. 2, the center land portion **31** includes the plurality of lug grooves **41** that pass through the center land portion **31** in the tire width direction and are disposed at predetermined intervals in the tire circumferential direction, and the plurality of blocks **51** partitioned by the lug grooves **41**. Also, a single block **51** is partitioned by a pair of circumferential main grooves **21**, **21** that are adjacent in the tire width direction, and a pair of lug grooves **41**, **41** that are adjacent in the tire circumferential direction. Also, the center land portion **31** is formed by these blocks **51** arranged as a row in the tire circumferential direction. Therefore, a single block **51** faces the left and right circumferential main grooves **21**, **21** that partition the center land portion **31**, and, the plurality of blocks **51** is arranged as a row in a straight line in the tire circumferential direction along the left and right circumferential main grooves **21**, **21**.

Also, as illustrated in FIG. 3, the lug grooves **41** of the center land portion **31** include a first lug groove portion **411** and a second lug groove portion **412**.

The first lug groove portions **411** are arranged intersecting the center line of each block **51** of the center land portion **31**. The center line of the block **51** is the straight line passing through the center point of the left and right maximum width positions of the block **51**, and is parallel to the tire circumferential direction. In the configuration in FIGS. 2 and 3, the center line of the blocks **51** is disposed on the tire equatorial plane CL.

Also, the groove width b of the first lug groove portion **411** is within the range of $2.0\text{ mm} \leq b \leq 5.0\text{ mm}$. Also, groove width b of the first lug groove portion **411** is set within the range such that the first lug groove portion **411** closes upon tire ground contact when the block **51** contacts the ground. Also, the groove width b of the first lug groove portion **411** is measured at the road contact surface of the land portion **31** when a new tire is assembled on a standard rim, inflated with the prescribed internal pressure, under no load conditions.

Ground contact conditions of the block **51** refers to the condition in which the tire contacts the surface of a flat plate when the tire is assembled on a standard rim, filled to the prescribed internal pressure, placed perpendicularly with respect to the flat plate in the static state, and loaded with a load corresponding to the prescribed load.

Herein, “standard rim” refers to an “applicable rim” defined by the Japan Automobile Tyre Manufacturers Association (JATMA), a “design rim” defined by the Tire and Rim Association (TRA), or a “measuring rim” defined by the European Tyre and Rim Technical Organisation (ETRTO). “Regular inner pressure” refers to “maximum air pressure” stipulated by JATMA, a maximum value in “tire load limits at various cold inflation pressures” defined by TRA, and “inflation pressures” stipulated by ETRTO. Note that “regular load” refers to “maximum load capacity” stipulated by JATMA, a maximum value in “tire load limits at various cold inflation pressures” defined by TRA, and “load capacity” stipulated by ETRTO. However, with JATMA, in the case of passenger car tires, the regular internal pressure is an air pressure of 180 kPa, and the regular load is 88% of the maximum load capacity.

Also, preferably, the angle of inclination α of the first lug groove portion **411** with respect to the tire width direction is within the range of $25\text{ (deg)} \leq \alpha \leq 65\text{ (deg)}$. The angle of inclination α is measured as the absolute value of the angle between the groove center line of the first lug groove portion **411** and the tire rotational axis.

Also, the distance D in the tire width direction of the first lug groove portion **411** and the width W of the block **51** have the relationship of $0.2 \leq D/W \leq 0.6$. The width W of the block **51** is measured as the maximum width in the tire width direction of the block **51**, when the tire is assembled on a standard rim and inflated with the prescribed internal pressure, under no load conditions.

The second lug groove portion **412** opens into one of the circumferential main grooves **21** from among the left and right circumferential main grooves **21**, **21** that partition the center land portion **31**. Therefore, the second lug groove portion **412** is configured as the opening of the lug groove **41** into the circumferential main groove **21**.

Also, the groove width B of the second lug groove portion **412** is within the range of $5.0\text{ mm} \leq B \leq 10.0\text{ mm}$. Also, the groove width b of the first lug groove portion **411** and the groove width B of the second lug groove portion **412** have the relationship of $b < B$. Therefore, the groove width B of the second lug groove portion **412** is wider than the groove width b of the first lug groove portion **411**. Accordingly, the opening of the lug groove **41** into the circumferential main groove **21** is widened by the second lug groove portion **412**. Also, the groove width B of the second lug groove portion **412** is set within the range such that the second lug groove portion **412** is not closed but remains open when the block **51** contacts the ground upon tire ground contact. Also, the groove width B of the second lug groove portion **412** is measured at the road contact surface of the land portion **31** when a new tire is assembled on a standard rim and inflated with the prescribed internal pressure under no load conditions.

Also, a single lug groove **41** includes the first lug groove portion **411** and the second lug groove portion **412** and is configured by connecting them. Also, the connecting portion between the first lug groove portion **411** and the second lug groove portion **412** may connect the narrower first lug groove portion **411** to the wider second lug groove portion **412** by widening the groove width in a step (see FIG. 3), or may connect the first lug groove portion **411** to the second lug groove portion **412** by gradually widening the groove width b (not illustrated on the drawings).

Also, the angle of inclination β of the second lug groove portion **412** with respect to the tire width direction is within the range of $0\text{ (deg)} \leq \beta \leq 25\text{ (deg)}$. Therefore, the angle of inclination β of the second lug groove portion **412** is less than or equal to the angle of inclination α of the first lug groove portion. The angle of inclination β is measured as the absolute value of the angle between the groove center line of the second lug groove portion **412** and the tire rotational axis.

For example, in the configuration in FIG. 3, the lug groove **41** is configured from the first lug groove portion **411** and a pair of second lug groove portions **412**, **412**. Also, the first lug groove portion **411** is disposed in the center of the land portion **31**, and intersects with the tire equatorial plane CL. Also, the first lug groove portion **411** has a straight line form, and has the groove width b as described above, the angle of inclination α with respect to the tire width direction, and a predetermined distance D in the tire width direction. Also, the pair of second lug groove portions **412**, **412** is configured as the left and right openings of the lug groove **41** disposed on the left and right edges of the land portion **31**, also, the pair of second lug groove portions **412**, **412** are each connected to

one of the two ends of the first lug groove portion **411**. Also, the second lug groove portions **412**, **412** have a straight line form, each has the groove width B as described above, and a predetermined angle of inclination β with respect to the tire width direction. Also, the angle of inclination α of the first lug groove portion **411** and the angle of inclination β of the second lug groove portions **412**, **412** have the relationship of $\alpha > \beta$, and, the first lug groove portion **411** and the second lug groove portion **412**, **412** are inclined in the same direction with respect to the tire width direction. Accordingly, the lug groove **41** has a bent shape overall, and has a shape with a narrow groove width in the first lug groove portion **411** in the center, and a broad groove width at the openings into the left and right circumferential main grooves **21**, **21**.

FIG. 4 is an explanatory view illustrating the effect of the pneumatic tire depicted in FIG. 1. FIG. 4 depicts the state of the blocks **51** and the lug grooves **41** during ground contact of the center land portion **31**.

In this pneumatic tire **1**, when the center land portion **31** contacts the ground, the blocks **51**, **51** deform in compression in the tire circumferential direction and the tire width direction due to the ground contact pressure. Therefore, the lug groove **41** becomes narrow, and the blocks **51** connect in the tire circumferential direction due to closure of the first lug groove portion **411** by mutual contact of the opposing groove wall surfaces of the first lug groove portion **411**. Accordingly, the stiffness in the tire circumferential direction of the center land portion **31** increases, and the tire rolling resistance is reduced. On the other hand, the second lug groove portion **412** has a wider structure than the first lug groove portion **411**, and the second lug groove portion **412** is disposed on the edge of the center land portion **31**, so the edge component of the center land portion **31** is ensured, and the tire snow braking performance is ensured. Accordingly, the tire rolling resistance performance and the snow braking performance are both achieved.

In the configuration of FIG. 2, the center land portion **31** on the tire equatorial plane CL from among the five rows of land portions **31** to **33** is provided with the lug grooves **41** having the first lug groove portion **411** and the second lug groove portion **412**. This configuration is preferable because the tire snow braking performance is effectively improved.

However, this is not a limitation, for example, in a configuration (not illustrated on the drawings) in which a circumferential main groove is disposed on the tire equatorial plane CL, the left and right land portions partitioned by the circumferential main grooves may have the first lug groove portion **411** and the second lug groove portions **412** as described above (not illustrated on the drawings). Also, some or all of the land portions from among the left and right second land portions **32**, **32** and the left and right shoulder portions **33**, **33** may have the first lug groove portion **411** and the second lug groove portions **412** as described above (not illustrated on the drawings).

Also, in the configuration in FIG. 2, the circumferential main grooves **21** that partition the center land portion **31** (the land portion that includes the lug groove **41** having the first lug groove portion **411** and the second lug groove portion **412**) extends while bending in the tire circumferential direction into a zigzag shape. In this configuration, the edge component of the center land portion **31** is increased, which is desirable in terms of improving the tire snow performance. However, this is not a limitation, and the circumferential main grooves **21** may have a straight shape (not illustrated on the drawings).

Also, in the configuration in FIG. 3, the first lug groove portion **411** and the second lug groove portion **412** have a

straight line shape. However, this is not a limitation, and the first lug groove portion **411** and the second lug groove portion **412** may have a circular arc shape, an S shape, a zigzag shape, and the like (not illustrated on the drawings). Also, the corner of the block **51** at the position of the intersection between the second lug groove portion **412** and the circumferential main groove **21** may have a radiused chamfer or a C-shaped chamfer (not illustrated on the drawings).

Also, in the pneumatic tire **1**, preferably, the groove depth H1 (not illustrated on the drawings) of the circumferential main grooves **21**, **21** that partition the center land portion **31** is in the range of $12\text{ mm} \leq H$. The upper limit on the groove depth of the circumferential main grooves **21** is restricted by the wall thickness of the tread rubber **15**. Also, the groove depth H1 of the circumferential main grooves **21** is measured as the maximum groove depth excluding any raised bottom portions or the like.

FIGS. **5** and **6** are explanatory views illustrating modified examples of the pneumatic tire depicted in FIG. **1**. In FIGS. **5** and **6**, a pair of blocks **51**, **51** that are adjacent in the center land portion **31** and a single lug groove **41** that is interposed between these blocks **51**, **51** have been extracted.

In the configurations of FIGS. **2** and **3**, the center of the first lug groove portion **411** extends the same length in the tire width direction centered on the point of intersection with the center line of the center land portion **31** (tire equatorial plane CL).

However, this is not a limitation, and as illustrated in FIG. **5**, the first lug groove portion **411** may be disposed biased in one direction in the tire width direction with respect to the center line of the center land portion **31**. Also, in this configuration, preferably, the first lug groove portion **411** is disposed so that it intersects the center line of the center land portion **31**. In this configuration, when the first lug groove portion **411** is closed and the adjacent blocks **51**, **51** become connected to each other during tire ground contact (see FIG. **4**), the stiffness of the center land portion **31** is effectively increased, and the tire rolling resistance is reduced.

Also, in the configuration in FIG. **3**, the lug grooves **41** have the second lug groove portions **412** at each opening into the left or right circumferential main grooves **21**, **21**. In this configuration, the left and right edge component of the center land portion is increased, which is desirable in terms of improving the tire snow braking performance.

However, this is not a limitation, and as illustrated in FIG. **6**, the lug groove **41** may have the second lug groove portion **412** only at an opening into one of the tire circumferential grooves **21**. In the configuration in FIG. **6**, the first lug groove portion **411** opens to the other of the circumferential main grooves **21**.

FIGS. **7** and **8** are explanatory views illustrating modified examples of the pneumatic tire depicted in FIG. **1**. In FIGS. **7** and **8**, a pair of blocks **51**, **51** that are adjacent in the center land portion **31** and a single lug groove **41** that is interposed between these blocks **51**, **51** have been extracted.

In the configuration of FIG. **3**, the first lug groove portion **411** of the lug groove **41** has groove wall surfaces with a straight line shape. In this configuration, when the first lug groove portion **411** is closed during tire ground contact, planar contact occurs between the left and right groove wall surfaces of the first lug groove portion **411**, and the adjacent blocks **51**, **51** become connected to each other (see FIG. **4**).

In contrast, as illustrated in FIGS. **7** and **8**, the opposing left and right groove walls of the first lug groove portion **411** may be configured to include protrusions and recesses **413** to **416**, so that the protrusions and recesses **413** to **416** engage with each other during ground contact of the blocks **51**. For

example, in the configuration of FIG. **7**, the first lug groove portion **411** includes a protrusion **413** on one of the groove wall surfaces and a recess **414** on the other of the groove wall surfaces, and the protrusion and recess **413**, **414** are configured so that they engage with each other during ground contact of the block **51**. Also, in the configuration of FIG. **8**, the first lug groove portion **411** has protrusions and recesses **415**, **416** with a zigzag shape on the left and right groove wall surfaces, and the protrusions and recesses **415**, **416** are configured so that they engage with each other during ground contact of the blocks **51**. According to these configurations, when the first lug groove portion **411** is closed and the adjacent blocks **51**, **51** become connected to each other during tire ground contact (see FIG. **4**), the stiffness of the center land portion **31** is effectively increased, and the rolling resistance of the tire is reduced.

Effect

As described above, the pneumatic tire **1** includes the plurality of circumferential main grooves **21** and **22** extending in the tire circumferential direction, and the plurality of land portions **31** to **33** partitioned by the circumferential main grooves **21** and **22** (see FIG. **2**). Also, at least one row of land portions **31** includes the plurality of lug grooves **41** that pass through the land portion **31** in the tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and the plurality of blocks **51** partitioned by the lug grooves **41**. Also, the lug groove **41** includes the first lug groove portion **411** and at least one second lug groove portion **412** that opens into one of the circumferential main grooves **21** (see FIG. **3**). Also, the groove width b of the first lug groove portion **411** and the groove width B of the second lug groove portion **412** have the relationship of $2.0\text{ mm} \leq b \leq 5.0\text{ mm}$ and of $b < B$ (see FIG. **3**). Also, these groove widths b, B are within ranges such that when the blocks **51** contact the ground, the first lug groove portion **411** is closed, but the second lug groove portion **412** is not closed but remains open (see FIG. **4**).

In this configuration, the first lug groove portion **411** has the narrow groove width b, so when the blocks **51** contacts the ground, the first lug groove portion **411** is closed and the blocks **51** become connected in the tire circumferential direction (see FIG. **4**). Accordingly, the stiffness in the tire circumferential direction of the center land portion **31** increases, and the tire rolling resistance is reduced. On the other hand, the wide second lug groove portion **412** is disposed at the edge of the center land portion **31**, so the edge component of the center land portion **31** is ensured, and the tire snow braking performance is ensured. Accordingly, there is the advantage that both the tire rolling resistance performance and the snow braking performance are achieved.

In particular, in this configuration, the lug groove **41** that passes through the land portion **31** in the tire width direction includes the first lug groove portion **411** and the second lug groove portion **412** described above, which has the advantage that the tire rolling resistance performance and the snow braking performance are effectively improved. For example, in a configuration (not illustrated on the drawings) having a circumferential narrow groove extending in a zigzag manner in the tire circumferential direction, even though, in an intermediate period of wear, the circumferential narrow groove could be closed during ground contact of the land portion, after the intermediate period of wear, the circumferential zigzag groove would not be closed, and the size of the individual blocks from which the center land portion is configured would become comparatively small, so there would be a problem of the occurrence of rapid wear of the center portion and uneven wear in the center portion blocks.

Also, in this configuration, the groove width b of the first lug groove portion **411** is made appropriate, so the tire rolling resistance performance and snow braking performance are improved. Also, this has the advantage that uneven wear in the land portion **31** is reduced and the uneven wear resistance performance of the tire is improved. In other words, by satisfying the relationship $2.0 \text{ mm} \leq b$, the snow braking performance is appropriately ensured, and by satisfying the relationship $b \leq 5.0 \text{ mm}$, the rolling resistance performance and uneven wear resistance performance are appropriately ensured.

Also, in the pneumatic tire **1** according to the present technology, the groove width B of the second lug groove portion **412** is within the range of $5.0 \text{ mm} \leq B \leq 10.0 \text{ mm}$ (see FIG. 3). In this configuration, the groove width B of the second lug groove portion **412** is made appropriate, which has the advantage that the tire rolling resistance performance, the snow braking performance, and the uneven wear resistance performance are all achieved. In other words, by satisfying the relationship $5.0 \text{ mm} \leq B$, the snow braking performance is appropriately ensured, and by satisfying the relationship $B \leq 10.0 \text{ mm}$, the rolling resistance performance and the uneven wear resistance performance are appropriately ensured.

Also, in the pneumatic tire **1**, a single block **51** is partitioned by the pair of circumferential main grooves **21**, **21** that are adjacent in the tire width direction, and the pair of lug grooves **41**, **41** that are adjacent in the tire circumferential direction (see FIG. 2). Also, the land portion **31** is formed by the plurality of blocks **51** arranged as a row in the tire circumferential direction. In this configuration, the land portion **31** is formed by the blocks **51** that are partitioned by the left and right circumferential main grooves **21**, **21** arranged as a row in the tire circumferential direction, and the lug grooves **41** are disposed between each block **51**, **51** and open into the left and right circumferential main grooves **21**, **21**. The lug groove **41** of the land portion **31** includes the first lug groove portion **411** and the second lug groove portion **412**, which has the advantage that the tire rolling resistance performance and the snow braking performance are effectively improved. For example, in a configuration (not illustrated on the drawings) in which the land portions are divided in the tire width direction by a circumferential narrow groove, even though the circumferential narrow groove is closed during ground contact of the land portion, the stiffness of that land portion in the tire circumferential direction is not sufficient, so the tire rolling resistance performance cannot be sufficiently obtained, which is not desirable.

Also, in the pneumatic tire **1**, the first lug groove portion **411** is disposed intersecting the center line of the block **51** (in FIG. 3, the tire equatorial plane CL) (see FIG. 3). In this configuration, during ground contact of the land portion **31**, the first lug groove portion **411** is closed, so the adjacent blocks **51**, **51** are connected at the center line of the block **51** (see FIG. 4). Accordingly, the stiffness of the land portions **31** is effectively increased, which has the advantage that the rolling resistance performance is improved.

Also, in the pneumatic tire **1**, the angle of inclination α of the first lug groove portion **411** with respect to the tire width direction is within the range of $25 \text{ (deg)} \leq \alpha \leq 65 \text{ (deg)}$ (see FIG. 3). In this configuration, the angle of inclination α of the first lug groove portion **411** is made appropriate, which has the advantage that the tire rolling resistance performance and the tire uneven wear performance are both achieved. In other words, by satisfying the relationship $25 \text{ degrees} \leq \alpha$, the uneven wear resistance performance is appropriately ensured. Also, by satisfying the relationship $\alpha \leq 65 \text{ degrees}$,

the rolling resistance performance and the uneven wear resistance performance are appropriately ensured.

Also, in the pneumatic tire **1**, the distance D in the tire width direction of the first lug groove portion **411** and the width W of the block **51** have the relationship of $0.2 \leq D/W \leq 0.6$ (see FIG. 3). In this configuration, the ratio D/W is made appropriate, which has the advantage that the tire uneven wear resistance performance and the snow braking performance are both achieved. In other words, satisfying the relationship $0.2 \leq D/W$ has the advantage that the uneven wear resistance performance is appropriately ensured, and satisfying the relationship $D/W \leq 0.6$ has the advantage that the snow braking performance is appropriately ensured.

Also, in the pneumatic tire **1**, the angle of inclination β of the second lug groove portion **412** with respect to the tire width direction is within the range of $0 \text{ (deg)} \leq \beta \leq 25 \text{ (deg)}$ (see FIG. 3). In this configuration, the angle of inclination β of the second lug groove portion **412** is made appropriate, which has the advantage that the tire uneven wear resistance performance is appropriately ensured.

Also, in the pneumatic tire **1**, the first lug groove portion **411** includes protrusions and recesses **413** to **416** disposed on the opposing left and right groove walls thereof and that engage with each other upon ground contact of the blocks **51** (see FIGS. 5 to 8). In this configuration, by providing the protrusions and recesses **413** to **416** in the groove walls of the first lug groove portion **411**, when the first lug groove portion **411** is closed during ground contact of the land portion **31**, the adjacent blocks **51**, **51** are strongly connected to each other. This has the advantage that the uneven wear resistance performance of the tire is improved.

EXAMPLES

FIGS. 9A-9B and 10A-10B are tables showing the results of performance testing of pneumatic tires according to the embodiment of the present technology.

In this performance testing, (1) rolling resistance performance, (2) snow braking performance, and (3) uneven wear resistance performance were evaluated for a plurality of different pneumatic tires (see FIGS. 9A-9B and 10A-10B). In these performance tests, pneumatic tires having a tire size of 275/80R22.5 were assembled on a standard rim of rim size 7.50×22.5, inflated to the maximum air pressure and the maximum load stipulated by JATMA was applied to the pneumatic tires.

(1) Evaluations related to rolling resistance performance were conducted by using a drum testing machine of drum diameter of 1707 mm to measure resistance force at a speed of 80 km/h. Results of the evaluations were indexed and the index value of the pneumatic tire of the conventional examples was set as the standard score (100). Higher scores were preferable. An index evaluation of 103 or higher was considered as superior.

(2) Evaluations related to the snow braking performance were conducted when driving a test vehicle on which the pneumatic tires were assembled over a snowy road surface at a snowy road test site, and the braking distance from a traveling speed of 40 km/h was measured. Based on the measurement results, index evaluation was carried out, using conventional examples as standards (100). In these evaluations, higher scores were preferable. An index evaluation of 103 or higher was considered as superior.

(3) Evaluations relating to the uneven wear resistance performance were conducted by driving a test vehicle on which the pneumatic tires were assembled over a paved surface for 100,000 km, and after completion, the uneven wear that

11

occurred in the center land portion was evaluated visually. Results of the evaluations were indexed and the index value of the pneumatic tire of the conventional examples was set as the standard score (100). Higher scores were preferable. An index evaluation of 103 or higher was considered as superior.

The pneumatic tires 1 of Working Example 1 to 16 had the configuration illustrated in FIGS. 1 to 3. Also, the groove width of the circumferential main grooves 21 was 9.0 mm, and the groove depth was 16.0 mm. Also, the width W of the blocks 51 was 65.0 mm.

The pneumatic tires according to Conventional Examples 1 to 4 had a uniform groove width ($b=B$) of the lug grooves 41 in the configuration of FIGS. 1 to 3. Specifically, in Conventional Examples 1 and 2, the lug groove 41 was a sipe, and in Conventional Examples 3 and 4, the lug groove 41 had a wide structure.

As can be seen from the test results, with the pneumatic tires according to Working Examples 1 to 16, the tire rolling resistance performance and snow braking performance were both achieved. In addition, it can be seen that the uneven wear resistance performance was improved by making the predetermined values appropriate.

What is claimed is:

1. A pneumatic tire, comprising: four or more circumferential main grooves extending in a tire circumferential direction; and five or more land portions partitioned by the circumferential main grooves,

a center land portion is defined as the land portion disposed on a tire equatorial plane, or the land portion partitioned by the circumferential main groove disposed on the tire equatorial plane,

the center land portion includes a plurality of lug grooves that pass through the center land portion in a tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and a plurality of blocks partitioned by the plurality of lug grooves,

the lug grooves including a first lug groove portion, and at least one second lug groove portion that opens into one of the circumferential main grooves,

a groove width b of the first lug groove portion and a groove width B of the second lug groove portion having relationships of $2.0\text{ mm} \leq b \leq 4.0\text{ mm}$ and $b < B$, and being within ranges such that upon ground contact of the blocks, the first lug groove portions are closed and the second lug groove portions are not closed but remain open,

the first lug groove portion and the second lug groove portion are inclined in a same direction with respect to the tire width direction,

an angle of inclination α of the first lug groove portion and an angle of inclination β of the second lug groove portion have a relationship of $\alpha > \beta$, and

a groove depth $H1$ of the circumferential main grooves is in the range of $12\text{ mm} \leq H1$.

2. The pneumatic tire according to claim 1, wherein the groove width B of the second lug groove portion is within the range of $5.0\text{ mm} \leq B \leq 10.0\text{ mm}$.

3. The pneumatic tire according to claim 1, wherein a single block is partitioned by a pair of circumferential main grooves that are adjacent in the tire width direction and a pair of lug grooves that are adjacent in the tire circumferential direction, and the land portion is formed by arranging a plurality of the blocks in a row in the tire circumferential direction.

4. The pneumatic tire according to claim 1, wherein the first lug groove portion is disposed intersecting with a center line of the blocks.

12

5. The pneumatic tire according to claim 1, wherein an angle of inclination α with respect to the tire width direction of the first lug groove is within a range of $25^\circ \leq \alpha \leq 65^\circ$.

6. The pneumatic tire according to claim 1, wherein a distance D in the tire width direction of the first lug groove portion and a width W of the block have the relationship of $0.2 \leq D/W \leq 0.6$.

7. The pneumatic tire according to claim 1, wherein an angle of inclination β with respect to the tire width direction of the second lug groove portion is within a range of $0^\circ \leq \beta \leq 25^\circ$.

8. The pneumatic tire according to claim 1, wherein the first lug groove portion includes protrusions and recesses disposed on opposing left and right groove walls and that engage with each other upon ground contact of the blocks.

9. The pneumatic tire according to claim 2, wherein a single block is partitioned by a pair of circumferential main grooves that are adjacent in the tire width direction and a pair of lug grooves that are adjacent in the tire circumferential direction, and the land portion is formed by arranging a plurality of the blocks in a row in the tire circumferential direction.

10. The pneumatic tire according to claim 2, wherein the first lug groove portion is disposed intersecting with a center line of the blocks.

11. The pneumatic tire according to claim 2, wherein an angle of inclination α with respect to the tire width direction of the first lug groove is within a range of $25^\circ \leq \alpha \leq 65^\circ$.

12. The pneumatic tire according to claim 3, wherein an angle of inclination α with respect to the tire width direction of the first lug groove is within a range of $25^\circ \leq \alpha \leq 65^\circ$.

13. The pneumatic tire according to claim 4, wherein an angle of inclination α with respect to the tire width direction of the first lug groove is within a range of $25^\circ \leq \alpha \leq 65^\circ$.

14. The pneumatic tire according to claim 2, wherein a distance D in the tire width direction of the first lug groove portion and a width W of the block have the relationship of $0.2 \leq D/W \leq 0.6$.

15. The pneumatic tire according to claim 3, wherein a distance D in the tire width direction of the first lug groove portion and a width W of the block have the relationship of $0.2 \leq D/W \leq 0.6$.

16. The pneumatic tire according to claim 4, wherein a distance D in the tire width direction of the first lug groove portion and a width W of the block have the relationship of $0.2 \leq D/W \leq 0.6$.

17. The pneumatic tire according to claim 2, wherein an angle of inclination β with respect to the tire width direction of the second lug groove portion is within a range of $0^\circ \leq \beta \leq 25^\circ$.

18. The pneumatic tire according to claim 3, wherein an angle of inclination β with respect to the tire width direction of the second lug groove portion is within a range of $0^\circ \leq \beta \leq 25^\circ$.

19. The pneumatic tire according to claim 2, wherein the first lug groove portion includes protrusions and recesses disposed on opposing left and right groove walls and that engage with each other upon ground contact of the blocks.

20. The pneumatic tire according to claim 3, wherein the first lug groove portion includes protrusions and recesses disposed on opposing left and right groove walls and that engage with each other upon ground contact of the blocks.

21. The pneumatic tire according to claim 1, wherein the angle of inclination α with respect to the tire width direction of the first lug groove is within a range of $45^\circ \leq \alpha \leq 65^\circ$.

13

22. The pneumatic tire according to claim 1, wherein the groove width b of the first lug groove portion is within a range of $2.0\text{ mm} \leq b \leq 3.5\text{ mm}$.

23. A pneumatic tire, comprising: four or more of circumferential main grooves extending in a tire circumferential direction; and five or more of land portions partitioned by the circumferential main grooves,

a center land portion is defined as the land portion disposed on a tire equatorial plane, or the land portion partitioned by the circumferential main groove disposed on the tire equatorial plane,

the center land portion includes a plurality of lug grooves that pass through the center land portion in a tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and a plurality of blocks partitioned by the plurality of lug grooves,

the lug grooves of the center land portion including a first lug groove portion, and at least one second lug groove portion that opens into one of the circumferential main grooves,

a groove width b of the first lug groove portion and a groove width B of the second lug groove portion having relationships of $2.0\text{ mm} \leq b \leq 5.0\text{ mm}$ and $b < B$, and being within ranges such that upon ground contact of the blocks, the first lug groove portions are closed and the second lug groove portions are not closed but remain open,

the first lug groove portion and the second lug groove portion are inclined in a same direction with respect to the tire width direction,

an angle of inclination α of the first lug groove portion and an angle of inclination β of the second lug groove portion have a relationship of $\alpha > \beta$,

a pair of left and right second land portions are defined as the land portions disposed outside of the center land portion in the tire width direction,

14

each of the second land portions includes a plurality of lug grooves that pass through the second land portion in a tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and a plurality of blocks partitioned by the plurality of lug grooves, and

upon ground contact of the blocks, the lug grooves of the second land portion are not closed but remain open.

24. A pneumatic tire, comprising: a plurality of circumferential main grooves extending in a tire circumferential direction; and a plurality of land portions partitioned by the circumferential main grooves,

the land portion in at least one row includes a plurality of lug grooves that pass through the land portion in a tire width direction and is disposed at predetermined intervals in the tire circumferential direction, and a plurality of blocks partitioned by the plurality of lug grooves,

the lug grooves including a first lug groove portion, and at least one second lug groove portion that opens into one of the circumferential main grooves, the first lug groove portion including protrusions and recesses disposed on opposing left and right groove walls that engage with each other upon ground contact of the blocks

a groove width b of the first lug groove portion and a groove width B of the second lug groove portion having relationships of $2.0\text{ mm} \leq b \leq 5.0\text{ mm}$ and $b < B$, and being within ranges such that upon ground contact of the blocks, the first lug groove portions are closed and the second lug groove portions are not closed but remain open,

the first lug groove portion and the second lug groove portion are inclined in a same direction with respect to the tire width direction, and

an angle of inclination α of the first lug groove portion and an angle of inclination β of the second lug groove portion have a relationship of $\alpha > \beta$.

* * * * *
